DRAFT

1.0 Introduction

On November 4 through November 6, 2015 the Missouri Department of Natural Resources (DNR) and Missouri Department of Health and Senior Services (DHSS) performed radiological surveys and sampling at locations in the vicinity of West Lake Landfill (site). The Environmental Protection Agency (EPA) also assisted in this event by providing additional equipment and staff. Sampling activities were conducted in publically accessible and private property areas near the perimeter of the site, as well as near residential areas, to determine if there is evidence of potential current exposures to the public. Where practical, the DNR performed gamma surveys to support selection of soil and sediment sampling at nine locations. Additionally, surface water sampling was performed at one location and settled dust swipe samples were collected at six locations. All dust swipe samples were analyzed using a bench top meter at the DNR's Florissant Field Office. Two of these samples along with all soil, sediment, and water samples were sent to the Eberline Services laboratory for further analysis. An interim summary report of this sampling effort was produced on January 25, 2016 and detailed the field screening and instrumentation information.

This final report updates the previous interim information and identifies the selected sampling locations, details the radiological survey and testing methods, presents all field and laboratory results, and includes recommendations based on all results. In a joint effort, the Missouri Department of Health and Senior Services performed radiological air sampling and will present their results separately from this report. All results are being shared with EPA, which is the lead regulatory agency for the radiologically impacted areas of the site. Overall, laboratory results identified private property that has two sample locations above EPA criteria for unrestricted use, which will require additional investigation. This finding is consistent with conclusions identified in EPA's 2008 OU-1 Record of Decision (EPA 2008.)

2.0 Site Description

The site is located on a parcel of approximately 200 acres within the city limits of Bridgeton, Missouri and was listed on the National Priorities List (NPL) in 1990 by EPA (Figure 1). The site consists of the Bridgeton Sanitary Landfill, which stopped receiving waste on December 31, 2004, and several old inactive areas with municipal solid waste and demolition debris. The site is divided into two Operable Units, or OUs. OU-1 consists of radiological areas (Area 1 and Area 2), and OU-2 consists of the other landfill areas, which are not known to be impacted by radionuclide contaminants.

The site is located approximately one mile north of the Interstate-70/270 interchange. The Missouri River lies approximately 2 miles north and west of the landfill and Lambert International Airport lies approximately 2 miles to the east-southeast. St. Charles Rock Road defines much of the eastern boundary of the site, with Boenker Lane/Old Saint Charles Road marking the southern and western boundaries.

3.0 Site Selection and Field Surveys

Preliminary sampling locations and areas of interest were selected during a field reconnaissance performed on October 20, 2015 and discussed in the November 2015 Radiological Survey and Sampling Plan (SAP). Selection was generally based on visual examination of the overall site's geographic layout with consideration given to:

- Historic sampling efforts listed in Appendix G;
- Prevailing wind direction at the site;
- Water drainage patterns;
- Evidence of erosion or sediment deposition; and
- Proximity to residential communities

After the preliminary reconnaissance and site selection, the sampling team returned to the selected locations on November 4 and utilized field equipment to screen each site in order to determine the need for further investigation in addition to selecting soil and sediment sampling locations. The previously published interim report provided a brief discussion of the sampling procedures and field investigation results as well as field logs and field notes of each sample location. This final report incorporates the results of the interim report and provides a full discussion of all the sampling procedures and results obtained during the investigation including laboratory sample analyses. Chain of Custody sheets and standard Level IV Report of lab analyses are available in Appendix D & E of this report.

Sampling and surveying was performed by four DNR personnel in groups of two. Where practical, soil samples taken from the sampling locations identified in Figure 1 were collected based on notable fluctuations in the radiological surveying equipment. Specifically, each soil sample collected came from locations exhibiting the highest readings in any one area, and thus biased the sampling location based on the highest gamma readings measured in the field results. Recorded weather data during the sampling event was either estimated based on hourly meteorological data provided by the DNR station located off of St. Charles Rock Road to the east of the site, or local data reported from a weather mobile phone application. Hourly meteorological data has been included in Appendix H.

Field and office equipment were used to survey sites for Alpha, Beta, and Gamma radiation. All types of radiation are present at low levels in the environment due to naturally occurring radionuclides. Therefore, radiation detection by the team's field equipment was expected. None of the results presented an immediate concern for worker safety; however, some dust swipe results warranted further laboratory analysis due to equipment response that deviated from what was typically encountered during the investigation. Equipment used for field measurements are summarized in Section 3.1.

3.1 Field and Bench-top Equipment Description

The equipment used for field measurements during this event is summarized below. Each item has been given a letter identifier which is referenced for the remainder of this report.

Equipment operation checks were performed consistent with standard operating procedures and numerous response verification checks were made during the sampling effort. Sampling equipment and tools were decontaminated consistent with standard operating procedures. Additional information for each piece of equipment is provided in Appendix F.

Equipment A: Ludlum model 2221 with 43-5 ZnS Scintillator detector - For this event, the meter was read as an instantaneous rate to search for hotspots, scan dust swipe samples prior to bench testing, and scan personnel at the end of daily sampling activities. Cumulative counts for 1 minute were taken when instantaneous readings detected any activity.

Equipment B: Ludlum model 2221 with 44-10 NaI Gamma Scintillator detector - The meter was utilized to collect instantaneous gamma readings of larger areas (gamma surveys) where practical in order to identify locations with values in the higher range of each area. One-minute readings of each identified location were then collected in order to select each soil and sediment sample location.

Equipment D: The Ludlum model 19A μ R meter probe was utilized for gamma surveys where soil and dust swipe samples were collected. The instrument was held horizontally near waist height. The instrument was preset to alarm at a reading of 50 μ R/hr, which represents an approximate annual exposure rate of 0.438 REM.

Equipment E: Ludlum model 2929 with 43-10-1 swipe counter - This bench top meter was used to perform alpha counts and combined beta-gamma counts of dust swipe samples. A Thorium 230 check source was periodically used to confirm equipment response.

EPA Equipment Y: Ludlum model 2221 with 44-20 NaI Gamma Scintillator detector – This field equipment was brought by and periodically used by EPA personnel at some sampling locations (Photograph 1.)

EPA Equipment Z: Ludlum model 3030 with ZnS (Ag) Scintillator detector and shielded 2-inch sample tray – This bench top meter and probe is owned by EPA and was used for simultaneous alpha and beta sample counts of selected dust swipe samples. Readings are in CPM for alpha and combined beta gamma.

3.2 Radiological Field Surveys

Radiological field surveys or “gamma” surveys were conducted where practical in order to obtain instantaneous data for an overall assessment of gamma radiation activity in an area. For all practical survey locations, the field team predominately surveyed areas exhibiting erosional and depositional features in order to improve the likelihood of biased soil sampling locations. Due to the discriminate nature of the performed surveys, the results by themselves do not provide sufficient data to draw any conclusions regarding the absence or the extent of the presence of surficial radiologically impacted material. However, the data can be used to indicate a need for further investigation and attempt to bias soil sampling locations. For soil sample locations, gamma survey readings were the first step in identifying what location to obtain a surface soil sample. For dust sample locations, gamma surveys were utilized to complement dust sample results in order to determine if additional investigation within the area may be warranted.

Procedure: For all soil and dust sample locations, equipment B or D was utilized to obtain instantaneous gamma readings where practical at sample areas identified in Figures 1 through 6. Locations within each area identified for soil sampling that had comparatively higher instantaneous readings were flagged for longer scans using equipment B. Some areas were surveyed several times, as shown in Table 4, during this sampling event. Photograph 2 shows an instantaneous gamma survey being conducted at Spanish Village Park.

Results: Survey values revealed the vast majority of instantaneous readings in each area fell in the lower range of the detected values for gamma radiation, with brief fluctuations to comparatively higher values. Gamma surveys around soil sample locations S03 and S06 were not practical due to the dense vegetation present in those areas. Soil sample locations S02, located on or immediately adjacent to restricted private property to the north, and S10, located on or immediately adjacent to restricted private property northwest of Area 2, had some persistent readings approximately 20% to 30% higher than other readings within the same area. The areas around S02 and S10 were subsequently surveyed again during the following day with equipment B and EPA Equipment Y to verify previous observations. Additional procedures for obtaining soil samples in addition to soil sample results are discussed in Section 3.3. Gamma surveys conducted in areas near dust sampling locations did not reveal significant observations. Table 4 displays the range of instantaneous gamma readings for all surveyed locations.

3.3 Settled Dust

Dust swipe samples were used in conjunction with gamma surveys as an additional screening tool. The use of dust or “smear” sampling provides a quick, semi-quantitative result for removable contamination. Each swipe was bench-tested for gross alpha and gross beta-gamma to assist in determining if additional investigation for an area may be warranted. As with field gamma surveys, swipe sampling has limitations that significantly affect the usability of data results (EPA 2011, Frame and Abelquist.) The dust swipe results from this investigation cannot by themselves confirm that removable radioactivity is absent in an area, only that removable radioactivity is present. In addition, swipe sampling and testing methods have considerable inefficiencies that make it difficult to accurately identify and quantify the activity on a sample. EPA 600/R-11/122 (EPA 2011) provides a detailed summary of the state of practice and inherent limitations of swipe sampling and methods.

Procedure: Dust swipe samples were obtained at each selected area using dry standard cloth swipes. A preliminary alpha scan of each swipe was performed using Equipment A prior to analyzing the swipe samples on Equipment E for 10-minute count duration alpha and beta - gamma counts. Photographs 7 and 8 show examples of dust sample collection and bench-top tests. Bench-top tests of dust swipe samples were performed first in order to obtain immediate and relatively inexpensive determination of potential presence and activity level of removable radioactive contamination. The results were compared to empty tray counts, and all samples that substantially deviated from empty tray values were flagged for additional analysis. As an additional quality control check, analysis using EPA equipment Z was performed on the flagged samples in addition to an equal number of samples exhibiting typical investigation results. The flagged samples were then sent to Eberline Laboratory for additional analyses. Laboratory results are discussed in Section 4.1.

Results: Eight locations were originally chosen for dust swipe samples, including two locations (D03 and D05) that had been previously tested by DNR on May 16, 2013. Of the eight planned locations, swipe samples were obtained for six locations, while two locations, D06 and D08 were not sampled due to site access or lack of adequate surface for sampling. A total of 18 swipe samples were collected from the six locations which are labelled first by the general location, then sequentially by letter for each separate object that was swiped. For example, all swipe samples collected at Spanish Village Park were identified as D04, and then each sample collected from separate locations at Spanish Village Park was labeled D04A, D04B, and D04C. DNR bench-top and quality control results are listed in Table 5 & 6.

Of the 18 samples analyzed, samples D05A and D07A were flagged for additional analysis. Sample D05A showed comparatively elevated alpha counts that incrementally decreased through each successive test down to values typically encountered during the

investigation. Sample D07A also showed comparatively elevated alpha count values that were sustained through each successive test. After being analyzed four times on Equipment E, these two samples, along with D04A and D01D for comparison purposes, were taken to EPA's local office for additional bench-top testing on November 16 using EPA Equipment Z. EPA bench-top tests generally did not confirmed the alpha results of Equipment E, but did indicate comparatively elevated beta counts based on EPA Equipment Z empty tray values, and ~~—~~ these results are presented in Table 7.

Based on screening results of D05A and the gamma survey, follow-up investigation for the immediate area was limited to laboratory analysis of D05A. Due to the proximity of sample locations S09 and S10 in addition to sampling in the immediate area by DHSS (MDHSS, 2016), follow-up investigation was limited to laboratory analysis of D07. Both samples D05A and D07A were sent to Eberline Services laboratory for additional analysis using non-destructive analytical techniques. The laboratory results are discussed in Section 4.1.

4.0 Laboratory Procedures and Results

Environmental media that were sampled and analyzed includes surface soil and sediment from zero to six inches below ground surface, surface water, and settled dust. Laboratory testing for soil and sediment include the following radionuclides of interest: Uranium-234 (U-234); U-235; U-238; Thorium-228 (Th-228); Th-230; Th-232; Radium-226 (Ra-226); Ra-228; and Lead 210 (Pb-210). Levels of Gross Alpha, Gross Beta and Gamma radiation were also examined. Laboratory testing for water samples includes total U, Ra-226, Ra-228, Gross Alpha, and Gross Beta. All radionuclides of interest are naturally occurring and will be present at low levels in the environment.

4.1 Laboratory Quality Assurance / Quality Control

Laboratory Quality Assurance and Quality Control (QA/QC) are necessary to enhance and document the quality and reliability of analytical data. While QA concentrates on the planning and implementation processes for establishing the reliability of laboratory data; QC procedures are the tools used to achieve data reliability. Accuracy and precision are important parameters for determining the quality and reliability of data provided by the lab.

Field QA/QC methods for sampling are detailed in DNR Federal Facility Section Quality Assurance Project Plan (QAPP) and Sampling Plan ~~(SAP)~~. A summary of, and rationale for field duplicate samples are summarized in this section.

Eberline Services laboratory performs a number of QA/QC checks that have been included in Eberline's Level IV reporting packet available in Appendix E. The QA/QC procedures assist in determining the error, minimum detectable activity (MDA), and qualifiers that are reported in the summarized tables within the report. A brief description of some of the QA/QC

protocol has been provided below to assist in distinguishing laboratory QA/QC data provided from Eberline's data packet from results of field samples.

Field Duplicate: A field duplicate (FD) is a separate sample collected at the same time and sampling location under identical conditions and then treated exactly the same throughout the laboratory processes. The results obtained for field duplicates give a measure of the precision associated with sample collection, preservation, storage as well as the analytical test methods used. These samples were labeled in the field similar to other samples, but noted on the Chain of Custody only as FD. For this study, field staff collected one field duplicate sample for each matrix. A total of one soil/sediment duplicate sample and one surface water duplicate were collected.

Laboratory Duplicate: A laboratory duplicate (DUP) is prepared by taking two sample portions from the same sample container and then processing and analyzing as two separate samples. Analysis results are used to measure analytical precision from the sample digestion/extraction step through the analysis process. One laboratory duplicate was analyzed for water samples, and two for soil/sediment samples.

Laboratory Method Blank: A method blank (MB) is prepared to represent the matrix as closely as possible without analytes of interest, and is prepared/extracted/digested and analyzed exactly like the field samples. Its purpose is to assess any contamination potentially introduced during sample preparation activities.

Laboratory Control Sample: A laboratory control sample (LCS) is a controlled matrix, known to be free of analytes of interest. Known analytes are then added or "spiked" to the controlled matrix at verified concentrations, and then analyzed using the same laboratory procedures. The LCS spiked sample results are then compared to the known value of the spike to evaluate the accuracy and performance of the analytical procedure, including all preparation and analysis steps.

4.2 Data Quality Objectives

The purpose of this investigation, as stated in the Sampling Plan SAP, is to determine if there is a current potential exposure to the public relative to the potential presence of radiologically impacted material at or near the ground surface. Our data quality objective is to provide sufficient sampling technique and analysis of sufficient quality, as outlined in DNR's QAPP and SAP, to incorporate generated data into ongoing radiological characterization activities at the West Lake Landfill site.

Due to the discriminate and limited nature of investigation activities discussed in this report, it would be inappropriate to use the laboratory results by themselves to make a determination of the absence of contamination within a broader area based on negative laboratory results. Similarly, positive laboratory results by themselves do not definitively determine the extent of contamination, and therefore do not quantify any potential radiological health risk within

the area in which a positive sample is obtained. Positive sample results may indicate the need for further characterization activity, or in other words, additional investigation regarding the presence and extent of contamination in the area in which the positive sample is found. Once an area is fully characterized, then a risk assessment can be made and health risks quantified. The results of this investigation can supplement on-going characterization activities currently being performed by the Potentially Responsible Parties (PRPs) ~~supplement additional characterization by incorporating these results into additional current~~ investigation activities.

4.3 Settled Dust

Procedure: As noted in Section 3.3, Samples D05A and D07A were sent to Eberline Services laboratory based on comparatively higher alpha counts. Eberline was initially requested to perform gross alpha and gross beta analysis on the samples in order to validate and quantify the results obtained during field testing. An informal gamma spectroscopy screening was requested for sample D07A in order to determine the source of beta activity detected from the initial analysis. Following the informal scan, a formal Low Energy Photon Spectroscopy (LEPS) analysis was requested.

The swipe sample laboratory results obtained during the investigation are compared to Nuclear Regulatory Commission (NRC) free release criteria for comparison (Table 1.) These criteria are used to assist in determining if NRC permitted facilities are sufficiently radiologically de-contaminated to be released for unrestricted use. The swiped surface area for each sample was variable and greater than 100 cm², but the resulting values have been compared to 100cm² surface area free release requirements as a conservative comparison.

Results: Samples D05A and D07A were tested by Eberline Services laboratory for Gross Alpha & Gross Beta using Method LANL MLR-100 Modified. A duplicate test on D05A was performed in addition to a laboratory control sample and method blank for quality assurance purposes. Quality assurance testing indicates acceptable results, and the results are summarized in Table 9. Overall, gross alpha and beta activity for all samples fall below NRC free release criteria (NRC, 1974). The Report of Analysis is available in Appendix E

After reviewing the results of the gross alpha and beta analysis, an informal gamma spectroscopy screening for D07A was requested in order to determine if the detected beta activity was potentially associated with radionuclides of interest or from activity associated with Potassium 40(K-40), a naturally occurring isotope that is not known to be associated with radiologically impacted material (RIM) originating from OU-1. Gamma screening with Canberra Gamma Apex software was performed, and based on the results of this informal scan, K-40 was ruled out as a primary beta emitter. Since Pb-210 was identified as a radionuclide of potential concern, a formal scan using LEPS

was requested and performed using Method LANL ER-130 Modified in order to determine if Pb-210 was the primary beta emitter. Laboratory results indicated potential lead-210 concentration, but the value was below Minimum Detectable Activity, and therefore is considered non-detect. Overall, gross alpha and beta activity for all samples fall below Nuclear Regulatory Commission free release criteria (NRC, 1974.) However, the results from sample D07A in combination with soil laboratory results and gamma surveys indicate a probable need for additional investigation in the area near dust sample location D07A.

Laboratory results of gross alpha and beta concentrations in Sample D05A, and the laboratory duplicate, were unremarkable so further isotopic analysis was not pursued. Bench-top results for Sample D05A and empty tray analysis during the second equipment check suggests that the activity may have been related to short-term changes in the testing environment. Rain occurring during this time may have affected the radon activity in the indoor environment where testing was performed.

Table 1: Laboratory Results of Selected Dust Swipe Samples Compared to Free Release Criteria

Sample ID	Laboratory measured Alpha* (dpm/100cm ²) ^A	Laboratory measured Beta* (dpm/100cm ²) ^A
D05A	1.35	2
D05A DUP	1.29	2.49
D07A	4.42	12.08
	FRC ^B : 20 dpm/ 100 cm ²	FRC ^B : 1000 dpm/ 100cm ²
* Laboratory results were reported in pCi/sample, and D05 results are J-coded or estimated values. A conversion factor of 1pCi = 2.22 dpm was used for comparison purposes		
^A Swipe area assumed to be equal to 100 cm ² . Actual swipe area was larger.		
^B FRC = NRC Free release criteria based on removable contamination (NRC, 1974)		

4.4 Surface Soil and Sediment

Procedure: As noted in section 3.2, equipment B and D were utilized to take area-wide instantaneous gamma readings of each soil sample location where practical. Based on the results of the gamma surveys, flags were placed in locations that had comparatively higher instantaneous values in each area. One-minute duration gamma readings using Equipment B were then collected for each flagged location (Photograph 3). Generally, six 1-minute measurements were taken for each area and the location with the highest reading was selected to collect the soil sample. Table 8 shows the instantaneous gamma ranges for each soil sample location in addition to 1-minute duration gamma counts performed in order to bias each soil and sediment sample.

Surface soil and sediment samples were collected using a slide hammer and split spoon sampler fitted with a plastic sleeve. The resulting sample, encased in a 2-inch diameter by 6-inch long plastic sleeve, was sealed on each end with a plastic cap then taped. (Photographs 4 - 5)

No difficulties were encountered with the field measuring or sampling tools. Some soil sampling locations were substantially moved from the original location selected during field reconnaissance due either to access issues or preferential selection based on surface erosional and depositional features. Sample location S02 located north of Area 2 appeared to contain crushed red brick debris which may have contributed to the comparatively elevated gamma readings, so an additional more segregated sample (S02B) was collected in an effort to potentially determine the source of the elevated gamma readings. An additional quality control field duplicate sample (S02C) was collected and sent for laboratory analysis.

Results: All samples including a quality control duplicate sample S02C were sent to Eberline Services for laboratory analysis. The following methods were used to analyze the soil and sediment samples:

- Isotopic Uranium (Uranium-234, -235, -238) – Method EML U-02 Modified;
- Isotopic Thorium (Thorium-228, -230, -232) – Method EML U-01 Modified;
- Radium – 226 – EPA Method 903.0 Modified;
- Radium – 228 – EPA Method 904.0 Modified;
- Lead – 210 – EML Pb-01 Modified; and
- Gross Alpha/Beta – LANL MLR-100 Modified

Quality control testing demonstrated acceptable precision and accuracy parameters. With some exceptions, Minimum Detectable Activities were generally low enough to quantify isotope concentrations. One notable exception was the U-235 Isotope. None of the results for U-235 were detected at concentrations higher than the detection limit and may be considered non-detect.

Table 2 provides a comparison of calculated results to EPA Unrestricted Use Criteria. Complete isotopic results are available in Table 10.

Table 2: Comparison of Soil Sample Results to Site-Specific Preliminary Remedial Goals

Soil Sample Results Compared to EPA Unrestricted Use Criteria ^A All units in pCi/g			
Sample ID	Thorium 230 + 232	Radium 226 + 228	Total Uranium
EPA Unrestricted Use value	7.9	7.9	54.5
WLL20151104-S01	3.1	2.3	1.8*
WLL20151104-S02	5.8	6.0	5.7*
WLL20151104-S02B	2.6	3.2	1.7*
WLL20151104-S02C (FD)	2.9	3.4	1.6*
WLL20151105-S03	3.8	3.4	1.8*
WLL20151105-S04	4.3	1.7*	1.6*
WLL20151104-S05	2.7	3.3	2.0*
WLL20151105-S06	1.7	2.4	1.6*
WLL20151106-S08	3.7	3.7	1.8*
WLL20151105-S09	9.2	3.6	1.9*
WLL20151104-S10	24.6	3.8*	2.0*
* Indicates one result was non-detect			
^A Reference value based on EPA Unrestricted Use Criteria			

Total radionuclide activity in soil sample S10 was notably more elevated compared to all other soil samples analyzed during the investigation. This sample contained a comparatively higher Pb-210 value than other sample results. In addition to exceeding EPA unrestricted use level for Th-230 + 232, over 65% of the total activity in the sample is associated with the Th-230 Isotope. Data suggest radiologically impacted material (RIM) is present in sample S10, and additional investigation in the area surrounding this sample location is warranted.

Total radionuclide activity in soil sample S09 were comparatively higher than total activity found in most other samples, and also exceeded EPA unrestricted use level for Th-230+232. Nearly half of the laboratory detected activity is associated with the Th-230 isotope. Soil sample S09 is located in proximity to soil sample S10 and dust sample D07, with all samples being on private property. Data suggest that RIM is present in the sample S09, and further investigation in the area surrounding sample location S09 is warranted.

Total radionuclide activity in soil sample S02 was also higher compared to typical activity found in other sample results for this investigation. It is noted that instead of having activity dominated by Th-230, the activity distribution of this sample was relatively even for thorium, radium and uranium isotopes, in addition to having the

highest activity from Pb-210 compared to all other samples. Sample S02 was observed to contain red brick material at the time of collection. Since brick material has been shown to be a potential source of radioactivity (Eichholz, et al, NUREG 1501), an additional sample (S02B) was collected in an attempt to isolate any potential source of activity. Laboratory results for sample S02B, without brick material observed in the sample, showed decreased activity similar to typical soil sample results found in the investigation. A comparison of these two results in addition to the field duplicate suggests that the brick material may be the source of radiological activity. However, red brick may be part of demolition debris originally located within West Lake Landfill, so RIM related activity cannot be conclusively ruled out. Since the laboratory results of a sample show activity of both Thorium and Radium near EPA unrestricted use levels, and the 1-minute gamma results of this area have readings that are higher than all other areas surveyed, additional investigation may be warranted.

Total radionuclide activity in soil sample S04 was roughly mid-range in comparison to other sample results from this investigation, and was below EPA unrestricted use levels for the WLL site. However, Th-230 activity accounted for a notable portion of the total activity, and may indicate some influence from a non-natural source. Additional confirmatory investigation or further fate and transport study may be warranted to characterize the presence of site related contaminants. This recommendation is due to only a single sample being collected, and that sample laboratory results indicate there is comparatively higher Thorium concentration in the sample than other soil sample results. This investigation may need to extend toward the area surrounding sample location S03, also referred as the North Surface Water or North Surface Water Body (McLaren/Hart 1996, EMSI 2000), which also showed slightly higher Th-230 activity compared to overall activity in the sample.

4.5 Surface Water

Procedure: One surface water sample and one field duplicate quality control sample was collected into 4-liter cubitainers for laboratory analysis. The water samples were obtained in the wooded area southwest of the site where water had collected during the November 5 rain event (Figure 6). Photograph 6 shows the samples being prepared for delivery. No problems were encountered during sampling.

Results: The following methods were used to analyze the water samples:

- Total Uranium – Method ASTM D5174 Modified
- Radium – 226 – EPA 903.0 Modified
- Radium – 228 – EPA 904.0
- Gross Alpha/Beta – EPA 900.0 Modified

Quality control testing demonstrated acceptable precision and accuracy parameters.

Overall, sample results for radiological contaminants of interest were below laboratory detection limits or below regulatory action and screening levels. Due to the stringent standards for drinking water, water sample results were compared to state drinking water standards, and provided in Table 3.

Table 3: Comparison of Water Sample Results to Drinking Water Regulations

Comparison of Water Sample Results to Drinking Water Regulatory Action Levels ^C				
	Combined Radium (pCi/L)	Total Uranium (µg/L)	Gross Alpha ^B (pCi/L)	Gross Beta pCi/L
Regulatory Action Level ^C	5	30	15	50 ^D
WLL20151105-W01	ND ^A	1.49	2.2	8.85
WLL20151105-W01 DUP	ND ^A	1.15	1.9	10.24
WLL20151105-W02 FD	ND ^A	ND ^A	ND ^A	10.10
^A Radionuclide activity was not detected above Minimum Detectable Activity, and is indicated as non-detect (ND) ^B Drinking water regulations assess Uranium limits separately from other Alpha emitters. Total Uranium activity was subtracted from Gross Alpha results in order to make an appropriate comparison. ^C 10 CSR 60-4.060 ^D Screening value for drinking water testing for beta activity minus K-40				

5.0 Conclusion

On November 4 through November 6, 2015 DNR and DHSS, with support from EPA, performed radiological surveys and sampling at locations in the vicinity of West Lake Landfill. Two dust swipe samples along with all soil, sediment, and water samples were sent to Eberline Services laboratory for further analysis. This final report updates the previous interim information and identifies the selected sampling locations, details the radiological survey and testing methods, presents all field and laboratory results, and includes recommendations based on all results.

Overall, all samples fell below site-specific action levels, with the exception of one general area comprised of two soil samples and a dust sample that indicated the presence of site-related contaminants above EPA's unrestricted use level. However, due to the discriminate and limited nature of investigation activities associated with this report, it would be inappropriate to use these results by themselves to make definitive statements regarding the absence, extent of presence, or potential health risk of radioactive contamination found at investigated sites.

Listed below are the recommendations of this effort as based on the results of this investigation.

1. Recommendation Requiring Additional Site Characterization; Soil Sample locations S09 & S10: Survey and sample data suggests that the area located immediately northwest of, and adjacent to OU-1 Area 2 requires additional characterization. The supporting data includes persistent comparatively higher values from gamma surveys, comparatively higher alpha and beta activity on dust swipe sample testing of D07A, and soil sample results from S10, and S09 that exceed EPA's unrestricted use levels. These sample results can supplement on-going characterization activities by incorporation into any additional investigation conducted by EPA and the potentially responsible parties PRPs. This conclusion is consistent with the need for additional investigation identified in EPA's 2008 OU-1 Record of Decision (EPA 2008)
2. ~~Recommendation of Inconclusive results suggesting further investigation-Confirmatory Sampling and Additional Characterization;~~ Soil Sample Location S02: Soil sampling results at location S02, while below site-specific action levels, did show comparatively higher activity levels. Laboratory results for sample S02B suggests the activity levels present in sample S02 may be attributable to brick material observed in the sample. However, given the limited number of samples collected from this area, and the unknown origin of the brick material, more investigation may be needed to confirm the cause, and potentially the extent of activity in this area.
3. ~~Recommendation of Confirmatory Sampling~~ Inconclusive results suggesting further investigation; Soil Sample Location S04: Although Sample S04 is below site specific action levels, confirmatory sampling of this area is recommended based on comparatively higher concentration of Th-230 activity, and the limited number of samples collected in proximity.

In conclusion, DNR has communicated all information and findings to EPA and any affected private property owners. This report will be posted to the Department's Westlake Landfill website. The DHSS radiological air sampling results will be presented in a separate report.

DRAFT

Appendix F: Radiological Field Equipment

Equipment A: Ludlum model 2221 with 43-5 ZnS Scintillator detector - The meter has both digital and analog scales, is able to provide both instantaneous rates and accumulative counts over a user set time, and has field adjustable voltage settings to give the user some flexibility in selection of probes and focusing on feedback at different energy levels to help evaluate readings. The 43-5 ZnS detector is an alpha radiation detector that requires very close proximity to the surface of the object being surveyed.

Equipment B: Ludlum model 2221 with 44-10 NaI Gamma Scintillator detector - The meter has both digital and analog scales, and is able to provide both instantaneous rates and cumulative counts over a user set time. The meter also has field adjustable voltage settings to give the user some flexibility in selection of probes and focusing on feedback at different energy levels to help evaluate readings. The 44-10 detector is a Sodium Iodide (NaI) gamma radiation detector that combines high sensitivity and fast response.

Equipment D: Ludlum model 19A μ R meter - This meter with built-in detector has a fixed logarithmic analog scale and can merely give feedback as a rate in units of micro-roentgen per hour (μ R/hr). It is meant to give fast and easy dose estimates in areas of low activity levels and to provide an alarm as activity begins to approach a preset action level. The instrument needle is constantly moving in response to activity such that visual precision is several μ R/hr. Results are most easily presented as a range.

Equipment E: Ludlum model 2929 with 43-10-1 swipe counter - This is a bench top meter and probe designed for counting swipe samples. These samples are small cloth patches used to retrieve dust. Readings are in total counts for alpha and combined beta gamma so readings need to be divided by the duration of the count in minutes for a CPM value.

EPA Equipment Y: Ludlum model 2221 with 44-20 NaI Gamma Scintillator detector – The 44-20 detector has higher detection sensitivity than Equipment B, making it well suited for survey applications (Photograph 1.)

EPA Equipment Z: Ludlum model 3030 with ZnS (Ag) Scintillator detector and shielded 2-inch sample tray – This was utilized as a bench top meter and probe used for simultaneous alpha and beta sample counting. Readings are in CPM for alpha and combined beta gamma.

Appendix G: Previous Investigations

Historic sampling and surveying efforts identified in the SAP that were considered for the current investigation:

- Late 1980's Department of Energy (DOE) Haul Road Sampling, 28 intersections (1994 DOE Remedial Investigation)
- 2005 MDNR Formerly Utilized Sites Remedial Action Program (FUSRAP) haul road sampling St. Charles Rock Road, Taussig, Boenker
- March 2013 EPA ASPECT Gamma and Infrared Survey
- May 2013 MDNR Radiological Survey, Alpha, Beta, Gamma survey/screening
- June 2013 DHSS Air Sampling, Alpha/Beta particulates, Ambient Gamma
- May 2014 EPA BMAC radiation survey and sampling
- 2014 EPA Community Air Monitoring, Gamma, Alpha/Beta Particulates, Radon
- April 2015 MO University of Science and Technology Phyto forensics
- May 2015 Respondents Air Monitoring, VOCs, Gamma, Alpha/Beta Particulates, Radon

Sample Event Log Information						
Project : West Lake Landfill Vicinity Sampling Event						
Sampling & Analysis Plan: West Lake Landfill Radiological Survey and Sampling Plan, November 3, 2015						
Purpose: Sample and Data Collection						
Date: November 4, 2015 Arrival Time: 15:56 Departure Time: 16:30						
Team members/responsibilities: Dan Covey - 2nd, sampler Rita Alexander, sampler, observations						
Weather (Description): Pt. cloudy	Temperature: 61 F	Humidity: 67%	Wind: (Direction and Speed) SE @ 12 mph			
Radiation detection equipment used: model/serial number/calibration:						
<input checked="" type="checkbox"/> Ludlum Model 2221 & 44-10 Detector/218595 & PR231843/October 20, 2015						
Time:	16:10					
Reading:	10577					
<input type="checkbox"/> Ludlum Model 2221 & 43-5 Detector/156999&PR155892/August 8, 2015						
Time:						
Reading:						
<input type="checkbox"/> Ludlum Model 19A/ 201916/June 25, 2015						
Range of Readings:						
Sample Collection Log Information						
Sample location description: Arthur training Pt E corner - 2nd sample & Dup.						
Odors Present: Yes or No		If Yes Please Describe:				
Collection equipment: Slide Hammer Split Spoon Sampler with Sleeve						
Sampler's name(s): Dan Covey Rita Alexander

11/4/15 0625 Westbase Landfill Vicinity Sampling
 Arrived @ Hessman's Trailer w/ Eric Gilstrap
 Met with CPE Personnel Adam Urbani
 EA Bill & signed off on BHA2
 Weather: cloudy, foggy, 59°F, 93% humidity, wind S @ 5 mph
 Diner's staff arrived @ 7:15
 CPE staff present: Tom Mahler 816-604-0546
 Diner's staff: Mary, Will, Brady, Shawn, Adam, Matt, Ben, Kevin
 Kevin's phone: 573-645-5143
 Remy Mahler, Louis Harris Franklin, Cory Jorgensen
 Marissa Reynolds, Nick Rosenberger, Jeremy Wilson
 Jonathan Garza, Brian Campbell
 Arrived @ Hessman's trailer @ 9:30
 Met Ryan Siebrange & Tom Mahler
 Ryan sample for @ 9:45
 Break for lunch @ 14:30 - 15:00
 Rainy day @ approx 16:00 & left area for
 Pleasant Field office
 All completed - All swipe samples &
 Soil samples from locs. S05, S01, S02 &
 S03
 All notes kept in field logs
 Pic taken - Equipment check more performed
 before & after sampling day
 Results kept in equipment log
 Book

11/5/15 West Lake Landfill Vicinity Sampling

2nd day WLL Vicinity Sampling

Arrived @ Florissant Field office @

8am to prep for sampling.

Left Florissant office in Dan Casey
for 1st loc @ N 0930.

1st loc SP4 @ V. Area. Met w Berry

Miller @ Virbree to gain Access.

Weather: cloudy, 11 rain, 64°F, 77% humidity

Tom Mauer wind @ 7 mph.

EPA joined us while @ Virbree

Followed us to Area SP13 (Arthur Truening)

+ SP10/SP9 - AAA Trucking Parking lots.

~~They~~ we observed our sample loc &

conducted some scans with their

3x3 radiation detection equipment.

Adam Schmitt & several people with the

AGC & GMP joined us briefly while @

AAA and left around 12:00. Dan Casey

I resumed sampling @ 12:00 with scan &

soil sampling @ SP9. Eric Gilstrap joined

us @ 13:15. I resumed in collecting sample

@ SP3 in ditch across St. Charles Rte Rd

from Jimmy Johns. 14:15-15:00 we broke for

lunch. Eric Gilstrap & I continued sampling

@ SP6, finishing & leaving area @ 17:30.

Rgt

84 11/16/15

Arrived @ 12:30 EPA Fenton, MO

Met Tom Mahler, EPA. Began QC check on
Ludlum

3030 equipment with lead shielding

Th 230 check source 19:00 down 12/1/03

SN# 5158-03 DMS-4

EPA SN# 0708-5023

Dr 5190-03 check source 5158-03 12/2/03

SN# 5158-03 DMS-14

SN# 770-3437

Th 230 c/s 1 min CR = 329 cpm 17% off

Dr 70 c/s 1 min CR = 9 = 1190 cpm 22% off

Machine average counts in cpm

10 min BG count: 0 (A) 142 (B) cpm

10 min α Alpha B = 0 cpm

Began cts @ 13:00 of 3030 samples

DØ4A: $\alpha = 0$ B = 45 cpm

DØ1D: $\alpha = 0$ B = 43 cpm

DØ5A: $\alpha = 0$ B = 43 cpm

DØ7A: $\alpha = 1$ B = 48 cpm

LI 3030 was calibrated by Ludlum 12/5/14

It is due for recalibration on 12/5/15

Serial # = 191249

Completed counts @ 14:15

Left EPA Fenton office @ 14:30

Raf
